Abstract

An MPI profiling library is a standard mechanism for intercepting MPI calls by applications. Profiling libraries are so named because they are commonly used to gather runtime information about performance characteristics. Here we present a profiling library whose purpose is to detect user errors in the use of MPI’s collective operations. While some errors can be detected locally (by a single process), other errors involving the consistency of arguments passed to MPI collective functions must be tested for in a collective fashion. While the idea of using such a profiling library does not originate here, we take the idea further than it has been taken before (we detect more errors, including those involving datatype inconsistencies) and present an open-source library that can be used with any MPI implementation. We describe the tests carried out, provide some details of the implementation, illustrate the usage of the library, and present performance tests.

Keywords: MPI, collective, errors, datatype, hashing

1 Introduction

One measure of the quality of a software system is its ability to identify user errors at an early stage and provide sufficient information for the user to correct the error. To this end, all high-quality implementations of the Message Passing Interface (MPI) Standard (Snir, Otto, Huss-Lederman, Walker, and Dongarra 1998; Gropp, Huss-Lederman, Lumsdaine, Lusk, Nitzberg, Saphir, and Snir 1998) provide for runtime checking of arguments passed
to MPI functions to ensure that they are appropriate and will not cause the function to behave unexpectedly or even cause the application to crash. The MPI collective operations, however, present a special problem: they are called in a coordinated way by multiple processes, and the Standard mandates (and common sense requires) that the arguments passed on each process be consistent with the arguments passed on the other processes. Perhaps the simplest example is the case of `MPI_Bcast`:

\[
\text{MPI\_Bcast}(\text{buff, count, datatype, root, communicator})
\]

in which each process must pass the same value for `root`. In this case, “consistent” means “identical,” but more complex types of consistency exist. No single process by itself can detect inconsistency; the error check itself must be a collective operation.

Fortunately, the MPI profiling interface allows one to intercept MPI calls and carry out such a collective check before carrying out the “real” collective operation specified by the application. In case of an error, the error can be reported in the way specified by the MPI Standard, still independently of the underlying MPI implementation, and without access to its source code.

The MPI profiling interface consists primarily of a requirement in the MPI Standard that all MPI functions (normally called by application programs using function names employing the “MPI” prefix) be also callable with a name using the corresponding “PMPI” prefix as well. This simple requirement allows a library writer, without access to the source code of the MPI implementation, to intercept all MPI calls by interposing at link time his own library of “MPI” functions, which carry out some useful specialized operation devised by the library writer. The specialized functions call “PMPI” functions required by the application. Such a special library of “MPI” functions is called a profiling library.

The profiling library we describe here is freely available as part of the MPICH2 MPI-2 implementation (MPICH2 Web Page ). Since the library is implemented entirely as an MPI profiling library, however, it can be used with any MPI implementation. For example, we have tested it with IBM’s MPI implementation for Blue Gene/L (Almási, Archer, Castaños, Gupta, Martorell, Moreira, Gropp, Rus, and Toonen 2003) and OpenMPI (OpenMPI Web Page ).

The idea of using the MPI profiling library for this purpose was first presented by Jesper Träff and Joachim Worringen in (Träff and Worringen 2004), where they describe the error-checking approach taken in the NEC MPI implementation, in which even local checks are done in the profiling library, some collective checks are done portably in a profiling library as we describe here, and some are done by making NEC-specific calls into the proprietary MPI implementation layer. The datatype consistency check in (Träff and Worringen 2004) is only partial, however; the sizes of communication buffers are checked, but not the details of the datatype arguments, where there is considerable room for user error. Moreover, the consistency requirements are not on the datatypes themselves, but on the datatype signatures; we say more about this in Section 3.1.

To address this area, we use a “datatype signature hashing” mechanism, devised by William Gropp in (Gropp 2000). He describes there a family of algorithms that can be used to assign a small amount of data to an MPI datatype signature in such a way that only small messages need to be sent in order to catch most user errors involving datatype arguments to MPI collective functions. In this paper we describe a specific implementation of datatype signature hashing and present an MPI profiling library that uses datatype
signature hashing to carry out more thorough error checking than is done in (Träff and Worringen 2004). Since extra work (to calculate the hash) is involved, we also present some simple performance measurements, although one can of course use this profiling library just during application development and remove it for production use. An earlier, compact version of this paper appeared in (Falzone, Chan, Lusk, and Gropp 2005).

In Section 2 we describe the nature and scope of the error checks we carry out and compare our approach with that in (Träff and Worringen 2004). Section 3 lays out details of our implementation, including our implementation of the hashing algorithm given in (Gropp 2000); we also describe how usage of the library is made convenient in the MPICH2 environment and show some example output. In Section 4 we present some performance measurements. Section 5 describes areas in which we intend to extend and improve the capabilities of the library. Section 6 summarizes the paper.

2 Scope of Checks

In this section we describe the error checking carried out by our profiling library. We give definitions of each check and provide a table associating the checks made on the arguments of each collective MPI function with that function. We also compare our collective error checking with that described in (Träff and Worringen 2004).

2.1 Definitions of Checks

The error checks for each MPI collective function are shown in Tables 1 and 2. There are five categories of tests; these are described below:

These checks apply to most collective routines:

call checks that all processes in the communicator have called the same collective function in a given event, thus guarding against the error of calling MPI_Reduce on some processes, for example, and MPI_Allreduce on others.
root means that the same argument was passed for the root argument on all processes.
datatype refers to datatype signature consistency. This test ensures both that the counts and the datatypes are consistent in the collective call. This is explained further in Section 3.1.

The following applies only to collective computation and some collective communication routines:

MPI_INPLACE means that every process either did or did not provide MPI_INPLACE instead of a buffer.

op checks operation consistency, for collective operations that include computations. For example, each process in a call to MPI_Reduce must provide the same operation.

The following apply only to intercommunicator create and merge:

local leader and tag test consistency of the local leader and tag arguments. They are used only for MPI_Intercomm_create.
high/low tests consistency of the high argument. It is used only for MPI_Intercomm_merge.

The following apply only to collective topology routines:

dims checks for dims consistency across the communicator.

graph tests the consistency of the graph supplied by the arguments to MPI_Graph_create and MPI_Graph_map.

The following apply only to collective I/O operations:

amode tests for amode consistency across the communicator for the function MPI_File_open.

size, datarep, and flag verify consistency on these arguments, respectively.

etype is an additional datatype signature check for MPI file operations.

order checks for the collective file read and write functions, therefore ensuring the proper order of the operations. According to the MPI Standard (Gropp, Huss-Lederman, Lumsdaine, Lusk, Nitzberg, Saphir, and Snir 1998), a begin operation must follow an end operation, with no other collective file functions in between.

One check that is not included in this table is that the same communicator is passed by each of the processes making the collective call, and that all processes in the communicator are making the call. An approach to handling this is proposed in Section 5.

2.2 Comparison with Previous Work

This work can be viewed as an extension of the NEC implementation of collective error checking via a profiling library presented in (Träff and Worringen 2004). The largest difference between that work and this is that we incorporate the datatype signature hashing mechanism described in Section 3, which makes this paper also an extension of (Gropp 2000), where the hashing mechanism is described but not implemented. In the NEC implementation, only message lengths, rather than datatype signatures, are checked. We do not check length consistency since it would be incorrect to do so in a heterogeneous environment. We also implement our library as a pure profiling library. This precludes us from doing some MPI-implementation-dependent checks that are provided in the NEC implementation, but allows our library to be used with any MPI implementation. In this paper we also present some performance tests, showing that the overhead, even of our unoptimized version, is acceptable. Finally, the library described here is freely available.

3 Implementation

In this section we describe our implementation of the datatype signature matching presented in (Gropp 2000). We also show how we use datatype signatures in coordination with other checks on collective operation arguments.

3.1 Datatype Signature Matching

In MPI, the amount of data to send or receive is described by the tuple \((\text{count}, \text{datatype})\) that indicates \(\text{count}\) copies of the \text{datatype} are used to describe the data. Because datatypes in MPI may be built from combinations of basic datatypes (such as \text{MPI\_INT}), the number of basic items that are communicated cannot be determined from the \text{count} alone. Instead, the number and type of basic types must be compared (basic types are just the MPI counterparts of the basic types in the language; e.g., \text{MPI\_INT} corresponds to the \text{C\_int} type). The basic types within an MPI datatype are called the \textit{MPI datatype signature} of that MPI datatype. More formally, an MPI datatype signature for a datatype constructed from \(n\) different basic datatypes \(type_i\) is simply

\[
\text{Typesig} = \{type_1, type_2, \ldots, type_n\}.
\]  
(1)

(In MPI, the \textit{type map} combines the information on the basic types and the displacement in memory that is to be used in reading or writing the data from or to memory; the displacement information is not relevant in our checks.)

A datatype hashing mechanism was proposed in (Gropp 2000) to allow efficient comparison of datatype signature over any MPI collective call. Essentially, it involves comparison
of a tuple \((\alpha, n)\), where \(\alpha\) is the hash value and \(n\) is the total number of basic predefined datatypes contained in it. A tuple of form \((\alpha, 1)\) is assigned for each basic MPI predefined datatype (e.g. MPI_INT), where \(\alpha\) is some chosen hash value. The tuple for an MPI derived datatype consisting of \(n\) basic predefined datatypes \((\alpha, 1)\) becomes \((\alpha, n)\). The combined tuple of any two MPI derived datatypes, \((\alpha, n)\) and \((\beta, m)\), is computed based on the hashing function:

\[
(\alpha, n) \oplus (\beta, m) \equiv (\alpha \land (\beta < n), n + m),
\]

where \(\land\) is the bitwise exclusive or (xor) operator, \(<\) is the circular left shift operator, and \(+\) is the integer addition operator. The noncommutative nature of the operator \(\oplus\) in equation (2) guarantees the ordered requirement in datatype signature definition (Equation 1).

One of the obvious potential hash collisions is caused by the \(<\) operator’s circular shift by 1 bit. Let us say there are four basic predefined datatypes identified by tuples \((\alpha, 1)\), \((\beta, 1)\), \((\gamma, 1)\), and \((\lambda, 1)\) and that \(\alpha = \lambda < 1\) and \(\gamma = \beta < 1\). For \(n = m = 1\) in equation (2),

Table 2: Checks performed on MPI-2 functions
we have

\[(\alpha, 1) \oplus (\beta, 1) \equiv (\alpha \land (\beta < 1), 2)\]
\[\equiv ((\beta < 1) \land \alpha, 2)\]
\[\equiv (\gamma \land (\lambda < 1), 2)\]
\[\equiv (\gamma, 1) \oplus (\lambda, 1),\]

If the hash values for all basic predefined datatypes are assigned consecutive integers, there will be roughly a 25 percent collision rate as indicated by equation (3). The simplest solution for avoiding this problem is to choose consecutive odd integers for all the basic predefined datatypes. Also, there are composite predefined datatypes in the MPI standard (e.g., \texttt{MPI\_FLOAT\_INT}), whose hash values are chosen according to equation (2) such that

\[
\texttt{MPI\_FLOAT\_INT} = \texttt{MPI\_FLOAT} \oplus \texttt{MPI\_INT}
\]

The tuples for \texttt{MPI\_UB} and \texttt{MPI\_LB} are assigned \((0, 0)\), so they are essentially ignored. \texttt{MPI\_PACKED} is a special case, as described in (Gropp 2000).

More complicated derived datatypes are decoded by using \texttt{MPI\_Type\_get\_envelope()} and \texttt{MPI\_Type\_get\_content()} and their hashed tuple computed during the process. Computing the hash value in the case where there “count” value is greater than one exploits the \(\log(n)\) algorithm described in (Gropp 2000).

While the simple hash function above is adequate for detecting mismatches of the basic datatypes, more sophisticated hash functions can be used that are more accurate for common derived datatypes. For example, see (Langou, Bosilca, Fagg, and Dongarra 2005) where computationally efficient hash functions based on Galois Fields are described and tested against a collection of MPI derived datatypes.

### 3.2 Collective Datatype Checking

Because of the different communication patterns and the different specifications of the send and receive datatypes in various MPI collective calls, a uniform method of collective datatype checking is not attainable. Hence five different procedures are used to validate the datatype consistency of the collectives. The goal here is to provide error messages at the process where the erroneous argument has been passed. To achieve that goal, we tailor each procedure to match the communication pattern of the profiled collective call. For convenience, each procedure is named by one of the MPI collective routines being profiled.

**Collective Scatter Check**

1. At the root, compute the sender’s datatype hash tuple.
2. Use \texttt{PMPI\_Bcast()} to broadcast the hash tuple from the root to other processes.
3. At each process, compute the receiver’s datatype hash tuple locally and compare it to the hash tuple received from the root.
A special case of the collective scatter check is when the sender’s datatype signature is the same as the receiver’s. This special case can be referred to as a collective bcast check. It is used in the profiled version of MPI_Bcast(), MPI_Reduce(), MPI_Allreduce(), MPI_Reduce_scatter(), MPI_Scan(), and MPI_Exscan.

The general collective scatter check is used in the profiled version of MPI_Gather() and MPI_Scatter().

**Collective Scatterv Check**

1. At the root, compute the vector of the sender’s datatype hash tuples.
2. Use PMPI_Scatter() to broadcast the vector of hash tuples from the root to the corresponding process in the communicator.
3. At each process, compute the receiver’s datatype hash tuple locally and compare it to the hash tuple received from the root.

The collective scatterv check is used in the profiled version of MPI_Gatherv() and MPI_Scatterv().

**Collective Allgatherv Check**

1. At each process, compute the sender’s datatype hash tuple.
2. Use PMPI_Allgather() to gather other senders’ datatype hash tuples as a local hash tuple vector.
3. At each process, compute the receiver’s datatype hash tuple locally, and compare it to each element of the hash tuple vector received.

The collective allgatherv check is used in the profiled version of MPI_Allgather() and MPI_Alltoall().

**Collective Allgatherv Check**

1. At each process, compute the sender’s datatype hash tuple.
2. Use PMPI_Allgather() to gather other senders’ datatype hash tuples as a local hash tuple vector.
3. At each process, compute the vector of the receiver’s datatype hash tuples locally, and compare this local hash tuple vector to the hash tuple vector received element by element.

The collective allgatherv check is used in the profiled version of MPI_Allgatherv().
Collective Alltoallv/Alltoallw Check

1. At each process, compute the vector of the sender’s datatype hash tuples.

2. Use `PMPI_Alltoall()` to gather other senders’ datatype hash tuples as a local hash tuple vector.

3. At each process, compute the vector of the receiver’s datatype hash tuples locally, and compare this local hash tuple vector to the hash tuple vector received element by element.

The difference between collective alltoallv and collective alltoallw checks is that alltoallw is more general than alltoallv; in other words, alltoallw accepts a vector of `MPI_Datatype` in both the sender and receiver.

The collective alltoallv check is used in the profiled version of `MPI_Alltoallv()`, and the collective alltoallw check is used in the profiled version of `MPI_Alltoallw()`.

3.3 Usage

In this section we illustrate how users enable the collective and datatype checking library when linking their applications in the case of MPICH; for other MPI implementations, they would follow the appropriate procedures for linking in profiling libraries.

The collective and datatype checking library is freely available as part of MPICH2 (MPICH2 Web Page) in the MPE subdirectory, along with other profiling libraries. MPE provides convenient compiler wrappers to allow for easy access of different profiling libraries. When MPE is installed separately with non-MPICH2 MPI implementation, e.g. IBM’s MPI for BlueGene/L or OpenMPI, two compiler wrappers, “mpecc” for C program and “mpfes” for Fortran program, are created. Available MPE profiling options for “mpecc” and “mpfes” are as follows; the option `-mpicheck` invokes the checks described in this paper.

```bash
-mpilog  : Automatic MPI and MPE user-defined states logging. This links against -llmpe -lmpe.

-mpitrace : Trace MPI program with printf. This links against -ltmpe.

-mpianim  : Animate MPI program in real-time. This links against -lampe -lmpe.

-mpicheck : Check MPI Program with the Collective & Datatype Checking library. This links against -lmpe_collchk.

-graphics : Use MPE graphics routines with X11 library. This links against -lmpe <X11 libraries>.

-log      : MPE user-defined states logging. This links against -lmpe.
```
-nolog : Nullify MPE user-defined states logging.
    This links against -lmpe_null.

-help : Print this help page.

To invoke the collective and datatype checking library, one can do

`mpecc -mpecheck -o mpi_pgm mpi_pgm.c`

Since MPICH2 provides a more comprehensive set of compiler wrappers, (mpicc, mpicxx, mpif77, and mpif90) than MPE’s, the MPE profiling options are available through a -mpe=[MPE option] switch provided by these wrappers, e.g. the following command will link the user program with the collective and datatype checking library.

`mpicc -mpe=mpicheck -o mpi_pgm mpi_pgm.c`

### 3.4 Example Output

We show here sample output (that would appear on stderr) from the collective and datatype checking library to indicate an incorrect use of MPI collective call.

**Example 1.** In this example, we run with four processes on MPICH2; all but the last process call MPI_Bcast; the last process calls MPI_BARRIER.

Starting MPI Collective and Datatype Checking

[cli_3]: aborting job:
Fatal error in MPI_Comm_call_errhandler:
Collective Checking: BARRIER (Rank 3) --> Collective call (BARRIER) is Inconsistent with Rank 0’s (BCAST).
rank 3 in job 4 jlogin1_42089 caused collective abort of all ranks
exit status of rank 3: return code 1

**Example 2.** In this example, run with four processes on MPICH2, all but the last process give MPI_INT to MPI_Bcast; the last process gives MPI_BYTE.

Starting MPI Collective and Datatype Checking

[cli_3]: aborting job:
Fatal error in MPI_Comm_call_errhandler:
Collective Checking: BCAST (Rank 3) --> Inconsistent datatype signatures detected between rank 3 and rank 0.
rank 3 in job 3 jlogin1_42089 caused collective abort of all ranks
exit status of rank 3: return code 1

**Example 3.** In this example, run with four processes on OpenMPI, all but the last process give MPI_INT to MPI_Bcast; the last process gives MPI_BYTE.

Starting MPI Collective and Datatype Checking

Collective Checking: BCAST --> no error
Collective Checking: BCAST --> no error
[jlogin1:09505] *** An error occurred in MPI_Comm_call_errhandler
[jlogin1:09505] *** on communicator MPI_COMM_WORLD
[jlogin1:09505] *** MPI_SUCCESS: no errors
[jlogin1:09505] *** MPI_ERRORS_ARE_FATAL (goodbye)
Collective Checking: BCAST --> Inconsistent datatype signatures detected between rank 3 and rank 0.

Example 4. In this example, run with four processes on MPICH2, all but the last process use 0 as the root parameter in MPI_Bcast; the last process uses its rank.

Example 5 In this example, run with four processes on OpenMPI, all but the last process use 0 as the root parameter in MPI_Bcast; the last process uses its rank.

4 Experiences

Here we describe our experiences with the collective error checking profiling library in the areas of usage, porting, and performance.

After preliminary debugging tests gave us some confidence that the library was functioning correctly, we applied it to the collective part of the MPICH2 test suite. This set
of tests consists of approximately 70 programs, many of which carry out multiple tests, which test the MPI-1 and MPI-2 Standard compliance for MPICH2. We were surprised (and strangely satisfied, although simultaneously embarrassed) to find an error in one of our test programs. One case in one test expected a datatype of one MPI_INT to match a vector of sizeof(int) MPI_BYTEs. That is, part of the code to test the use of datatypes contained the fragment:

```c
sendtype->datatype = MPI_INT;
sendtype->count = 1;
recvtype->datatype = MPI_BYTE;
recvtype->count = sizeof(int);
```

This is incorrect, although MPICH2 allowed the program to execute.

To test a real application, we linked FLASH (Rosner, Calder, Dursi, Fryxell, Lamb, Niemeyer, Olson, Ricker, Timmes, Truran, Tufo, Young, Zingale, Lusk, and Stevens 2000), a large astrophysics application utilizing many collective operations, with the profiling library and ran one of its model problems. In this case no errors were found.

A profiling library should be automatically portable among MPI implementations. The library we describe here was developed under MPICH2. To check for portability and to obtain separate performance measurements, we also used it in conjunction with IBM’s MPI for BlueGene/L (Almási, Archer, Castaños, Gupta, Martorell, Moreira, Gropp, Rus, and Toonen 2003) and OpenMPI (OpenMPI Web Page ; Gabriel, Fagg, Bosilca, Angskun, Dongarra, Squyres, Sahay, Kambadur, Barrett, Lumsdaine, Castain, Daniel, Graham, and Woodall 2004), without encountering any problems. However, we noticed that incorrect MPI collective programs sometimes behaved differently on different implementations. This is perfectly acceptable, since the MPI Standard does not specify the behavior of erroneous programs. But it does make it particularly useful to identify and report such errors before the actual collective call takes place.

We carried out performance tests on three platforms. On BlueGene/L, the collective and datatype checking library and the test codes were compiled with xlc of version 8.0 and linked with the IBM’s MPI implementation (V1R3M1_400_2006-061024) available on BlueGene/L.

The performance of the collective and datatype checking library of a 32-process job is listed in Table 3, where each test case is linked with and without the collective and datatype checking library.

Similarly on a IA32 Linux cluster, the collective and datatype checking library and the test codes were compiled with gcc of version 4.0.2 and linked with MPICH2-1.0.5 and OpenMPI-1.1.2. The performance results of the library are tabulated in Table 4 and 5.

Tables, 3, 4 and 5, show that the relative cost of the collective and datatype checking library diminishes as the size of the datatype increases. The cost of collective checking can be significant when the datatype size is small. One would like the performance of such a library to be good enough that it is convenient to use and does not affect the general behavior of the application it is being applied to. On the other hand, performance is not absolutely critical, since it is basically a debug-time tool and is not likely to be used when the application is in production. Our implementation at this stage does still present a number of opportunities for optimization, but we have found it highly usable.

Table 3: The maximum time taken (in seconds) among all the processes in a 32-process MPI job on BlueGene/L, where count is the number of MPI_Doubles in the datatype, and $N_{itr}$ refers to the number of times the MPI collective routine was called in the test. The underlined digits indicates that the corresponding digit could be less in one of the processes involved.

5 Future Work

We are pursuing a number of extensions and enhancements to this collective error-checking library. With respect to the current implementation, we need to forward any error returns from the MPI library to the user when the error handler is not MPI_ERRORS_ABORT; this is particularly true when MPI_ERRORS_RETURN has been selected as the error handler for MPI routines.

In an MPI-2 environment, we can reduce the cost of comparing datatype signatures by making use of the attribute caching functions to save the hash value on the MPI datatype; thus we only need to compute the hash function once for a derived datatype. This can be done when the datatype is committed with MPI_Type_commit, reducing the cost within the collective routines.

A similar approach for detecting datatype mismatches can be applied to point-to-point operations. In this case, we would also like to enable the option of an implementation-specific approach, as it is relatively easy to include the datatype hash value in the message.

envelope used within the MPI implementation. Of course, we will provide a fully portable version that does not rely on interfacing with the internals of the MPI implementations.

One weakness of our approach is that it assumes that all processes in the communicator are calling a collective operation. While we do check for the error of calling different collective operations on the same communicator, we do not check for calling collective operations on different communicators. For example, consider this code fragment in a single-threaded program:

```c
MPI_Comm_split( ..., &comm1 );
MPI_Comm_split( ..., &comm2 );
if (rank < size/2) {
    MPI_Bcast( ..., comm1 );
    MPI_Bcast( ..., comm2 );
} else {
    MPI_Bcast( ..., comm2 );
    MPI_Bcast( ..., comm1 );
}
```

While something so clearly wrong is unlikely to occur so obviously in a code, this set of collective operations could occur as a result of complex (and erroneous) logic in managing several communicators, such as communicators for row and column computations in a matrix. Our library will not catch these; instead, a deadlock will occur within the collective operations that we use to implement the checks. To catch these errors, it is necessary to use point-to-point operations on a private communicator. In MPI-1 programs, this can be accomplished by creating a dup of `MPI_COMM_WORLD` and using a point-to-point implementation of an Allreduce operation to compare a communicator id, also maintained by the colcheck library, to ensure that collective operations are properly ordered in the MPI code. By using nonblocking operations and implementing a time-out, we can also handle errors where some processes do not make a collective call at all, as in this example:

```c
if (rank == 0) MPI_Bcast( ..., 0, MPI_COMM_WORLD );
else MPI_Recv( ..., 0, MPI_COMM_WORLD );
```

(This error is seen when a user uses `MPI_Bcast` as if it is a “SendAll” instead of an MPI
collective operation.)

Multithreaded programs introduce additional complexity. For example, the above mechanism for detecting mismatched use of communicators in collective calls is no longer valid because different threads are permitted (and in fact are encouraged) to make MPI collective calls on different communicators. Detecting user errors, such as the use of MPI\_Bcast as a “SendAll”, will require either a timeout check (with an arbitrary, user-controllable timeout period) or more sophisticated deadlock detection, such as determining that every MPI thread (not just process) is in a blocking wait.

Finally, while the performance overhead for this profiling library is probably acceptable for use in testing rather than production runs, the current implementation admits of optimizations that have not yet been carried out. The optimizations with the most impact are those which will reduce the number of “extra” collective operations carried out by the checking library.

6 Summary

In this paper we have described an effective technique for MPI programmers to use for detecting easy-to-make but hard-to-find mistakes that often lead to deadlock, incorrect results, or worse. The technique demonstrates an important use of the MPI “profiling library” idea. We have demonstrated the library’s portability by running it with three different MPI implementations and measuring its performance. We have implemented the datatype hashing algorithm presented elsewhere and demonstrated its effectiveness. Our final section outlines future improvements that are under way.
